Regularly record, track, monitor and test all access logs to network and workstations

Summary:
The use of logging mechanisms is critical in preventing, detecting and minimizing the impact of data compromise. If system usage is not logged, potential breaches cannot be identified. Secure, controlled audit trails must therefore be implemented that link all access to system components with individual users and log their actions. This includes access to cardholder data, actions taken by individuals with root or administrative privileges, access to audit trails, invalid logical access attempts, use of and changes to identification and authentication mechanisms, the initializing, stopping or pausing of audit logs, and the creation and deletion of system-level objects. An audit trail history should be retained for at least a year, with a minimum of three months' logs immediately available for analysis. Logs and security events should be regularly reviewed to identify anomalous or suspicious activity.

Lab Setup:

Security onion is collecting log data from all of the systems on the network. In this exercise we will be filtering these logs to confirm compliance with user authentication and privileged access. We can build filters to search for privileged user logon times and locations to ensure actual user permissions reflect written policy.

PCI_DSS Mapping:

10.2.1 All individual user accesses to cardholder data.
10.2.2 All actions taken by any individual with root or administrative privileges.
10.2.3 Access to all audit trails.
10.2.4 Invalid logical access attempts.
10.2.5 Use of and changes to identification and authentication mechanisms—including but not limited to creation of new accounts and elevation of privileges—and all changes, additions, or deletions to accounts with root or administrative privileges.
Windows logon session process:

We need to understand the order that the windows EventLog uses to represent the logon process for an interactive user account. From that point we can figure out:

- Logon time
- Logout time
- Login locally or remotely
- Was this a standard user or admin

Questions we can answer from viewing the logs of the logon process:

<table>
<thead>
<tr>
<th>Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use this field to tie together all of the logon session events</td>
</tr>
</tbody>
</table>
| ```
data.EventChannel.EventData.TargetLogonId
```

<table>
<thead>
<tr>
<th>Who Logged In</th>
</tr>
</thead>
</table>
| ```
data.EventChannel.EventData.TargetUserName
```

<table>
<thead>
<tr>
<th>All groups User Is In</th>
</tr>
</thead>
</table>
| ```
data.EventChannel.EventData.GroupMembership
```

<table>
<thead>
<tr>
<th>What Did They Log Into</th>
</tr>
</thead>
</table>
| ```
data.EventChannel.EventData.WorkstationName
```

<table>
<thead>
<tr>
<th>When Did they Login</th>
</tr>
</thead>
</table>
| ```
data.EventChannel.System.SystemTime
```

<table>
<thead>
<tr>
<th>When Did they Logout</th>
</tr>
</thead>
</table>
| ```
data.EventChannel.System.SystemTime
```
Windows Logs:

There are many fields contained in the Windows Event logs. This information can be used to confirm that a logon policy is being properly enforced or later to correlate a user's logon session with other activity on a system.

Common logon session events:

<table>
<thead>
<tr>
<th>event_id</th>
<th>data.EventChannel.System.Message</th>
</tr>
</thead>
</table>
| 4624     | An account was successfully logged on  
(successful attempt to logon to the local computer regardless of logon type, location of the user or type of account)  
Note: Use “TargetLogonId” to tie this to the rest of the session |
| 4625     | This identifies the user that attempted to logon and failed. |
| 4627     | Group membership information  
(One or more of these events are logged whenever a user logs on or a logon session begins for any other reason)  
Note: Use “TargetLogonId” to tie this to the rest of the session |
| 4634     | An account was logged off |
| 4647     | User initiated logoff  
Used during interactive logons when the user logs out  
Note: Use “TargetLogonId” to tie this to the rest of the session |
| 4672     | Special privileges assigned to new logon  
Whenever an account assigned any "administrator equivalent" user rights logs on. (This will be close to 4624 when an admin logs in). |
**In Kibana:**

**Key Fields for Parsing Authentication Events:**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Metadata about the Event</strong></td>
<td></td>
</tr>
<tr>
<td><code>event_id</code></td>
<td>The Windows Event ID</td>
</tr>
<tr>
<td><code>data.EventChannel.System.SystemTime</code></td>
<td>The Time an Event was logged to the windows machine (Remember all times on Sec Onion are UTC) vs likely timezone setting on Windows machine.</td>
</tr>
<tr>
<td><strong>New Logon Info: The user who just logged on</strong></td>
<td></td>
</tr>
<tr>
<td><code>data.EventChannel.EventData.TargetUserName</code></td>
<td>User Account Name. Note: Can be a logon account or a system account.</td>
</tr>
</tbody>
</table>
| `data.EventChannel.EventData.TargetDomainName` | Domain name of the account in either the DNS name (can be upper or lowercase) or pre-Win2k NETBIOS domain name. **Local User Account** = Name of the Computer **Domain User Account** = Name of the Domain Security principal accounts  
  - SYSTEM = "NT AUTHORITY"  
  - LOCAL SERVICE = "NT AUTHORITY"  
  - NETWORK SERVICE = "NT AUTHORITY"  
  - ANONYMOUS LOGON = "NT AUTHORITY"  
  Virtual Accounts = "NT Service" |
| `data.EventChannel.EventData.TargetUserSid` | SID of the account |
| `data.EventChannel.EventData.LogonType` |  
  - 2 = Interactive (logon at keyboard and screen of system)  
  - 3 = Network (Mapped Drive/failed RDP)  
  - 10 = Remote Interactive (Terminal Services, Remote Desktop or Remote Assistance)  
  There are more login types but for the scope of this lab these will do. |
| `data.EventChannel.EventData.ElevatedToken` | Elevated Token:  
  - Yes = %%%%1842 |
<table>
<thead>
<tr>
<th>Data Event Channel: Event Data</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data.EventChannel.EventData.TargetLogonId</td>
<td>A semi-unique (unique between reboots) number that identifies the logon session just initiated. Any events logged subsequently during this logon session will report the same Logon ID through to the logoff event 4647 or 4634.</td>
</tr>
<tr>
<td>data.EventChannel.EventData.IpAddress</td>
<td>The IP address of the computer where the user is physically sitting (unless this logon was initiated by a server application acting on behalf of the user).</td>
</tr>
</tbody>
</table>

**Network Information: If the user logged in remotely**

- If logon is initiated on local machine
  - IP = 127.0.0.1
  - IP = actual local IP address.
Basic Search strings:

To find a specific event_id:

> event_id:<id number>

To find all Events for a given user:

> data.EventChannel.EventData.TargetUserName:"Administrator"

We can also chain multiple queries together by using “AND”

To find all successful local logon attempts:

> data.EventChannel.EventData.LogonType:2 AND event_id:4624

To find all failed local logon attempts:

> data.EventChannel.EventData.LogonType:2 AND event_id:4625

To find all successful Remote Desktop logon attempts:

> data.EventChannel.EventData.LogonType:10 AND event_id:4624

To find all failed Remote Desktop logon attempts (Note: Type 3):

> data.EventChannel.EventData.LogonType:3 AND event_id:4624

To filter out the “SYSTEM” account from your results:

> event_id:4624 AND NOT data.EventChannel.EventData.TargetUserName:"SYSTEM"

To find all successful logon attempts with Elevated Privileges:
(Note: this will show ALL accounts including “SYSTEM” type accounts)

> data.EventChannel.EventData.ElevatedToken:%%1842
Policy option we need to confirm:

Although we can extend this exercise, our goal here is to confirm compliance with actions taken by individuals with root or administrative privileges, access to audit trails, invalid logical access attempts. We want to make sure that there are no accounts logging in with privileges not defined in our policy. As such we will be checking for

- Successful logins
- Failed logins
- Logins with admin privileges

Test to ensure the policy is being followed.
1. Only the Administrators account should be able to logon locally to the Win2016 server.
2. Too many failed logon attempts should be looked at as potential attack.
3. Only the Administrators account should have administrative privileges
Audit HowTo:

Building filter (Type it in):

So to find an audit trail for any users who logged in locally with elevated (admin) privileges.

To find all successful local logon attempts with Elevated (Admin) Privileges:

```plaintext
>_ data.EventChannel.EventData.LogonType:2 AND
data.EventChannel.EventData.ElevatedToken:%%1842
```

Once we have found the logon success event we are looking for we can find the rest of the logon/logoff process using the “TargetLogonId”. Once you set the TargetLogonId you will need to remove all of the other filters so you can see all events associated with the logon session.

Note: Sometimes you can not find the logoff event if the system was shutdown while the user was logged in (often the case with educational VM’s but not so much on a real production network).

Note: Your ID will vary.

```plaintext
>_ data.EventChannel.EventData.TargetLogonId:0x34d1c3
```

This will get us:

- event_id:4624
- event_id:4647
Building filter (Use the Wizard):

Step 1) Create the EventID filter: This will find all successful logon attempts.

Step 2) Look for LogonType
- 2 = Local logon
- 10 = Remote Desktop
Step 3) Look for any accounts that were given admin privileges.

- %1842 = Member of the administrators group
- %1843 = Not a member of the administrators group

Step 4) Search for specific account name:
ToDo:

1. Find how many times the “Administrator” account successfully log on.
   ________________________________________________________________

2. Find how many times the “Administrator” account unsuccessfully log on.

3. From looking at the records, what is the only machine that has ever had the “Administrator” account log into it? _____________________________

4. Have any machines been logged into using “Remote Desktop”: ____________

5. Which ones: ______________________________________________________

6. What user/users logged into it: _______________________________________

7. How long was the user logged in: ________________________________
   Note: This one can be hard or impossible depending on how the user exited the RDP session
